

AZ Permit Radar — Revised Product and Business Charter

1. Product definition

AZ Permit Radar is an Arizona-focused construction intelligence platform that collects newly published permit information from local government sources, converts the records into normalized and trade-relevant opportunities, and delivers those opportunities to qualified construction businesses.

AZ Permit Radar is not initially a permit-submission platform, contractor CRM, bidding marketplace, or general construction database.

Its primary job is to reduce the time between the public issuance of a permit and a relevant Arizona business discovering and acting on the opportunity.

2. Initial market position

AZ Permit Radar will compete through:

1. Arizona specialization.
2. Faster source monitoring.
3. Better trade-specific filtering.
4. Clear explanations of why a permit is relevant.
5. Mobile-friendly alerts and workflows.
6. Transparent links to original public records.
7. Responsive support for local businesses.

It will not initially compete through national coverage, maximum record volume, large enterprise integrations, or proprietary contact databases.

3. Initial ideal customer profile

The initial customer is an Arizona subcontractor, supplier, equipment rental company, or construction-related sales organization that:

- Serves a defined geographic territory.
- Targets identifiable project or permit types.
- Has recurring capacity for new work.
- Currently relies on referrals, public record searches, networking, purchased lists, or manual prospecting.
- Can assign someone to review and act on qualified opportunities.
- Gains meaningful value from learning about a project earlier.

Initial pilots should focus on one geographic market and approximately two trade categories.

4. User jobs to be done

Customers hire AZ Permit Radar to:

- Discover relevant projects before competitors.
- Avoid manually reviewing municipal reports.
- Filter projects outside their trade or territory.
- Prioritize higher-value opportunities.
- understand why a project was selected.
- Receive important opportunities without repeatedly checking a dashboard.
- Maintain a lightweight record of opportunities they saved, dismissed, or contacted.

5. Product promise

For every opportunity, the platform should clearly communicate:

- What occurred.
- Where it occurred.
- When the source published or approved it.
- Which trade categories may be relevant.
- Why it matched the customer.
- How confident the system is.
- What public source supports the information.
- What the customer can do next.

6. MVP product surface

Public website

- Professional landing page.
- Arizona-specific explanation.
- Clear product promise.
- Example opportunity card.
- Explanation of data freshness and source traceability.
- Sign-up and login.
- Pilot or demo call to action.

Onboarding

Collect only information necessary to produce useful matches:

- User name.
- Business name.
- Email.

- Verified phone number when SMS is enabled.
- Primary and secondary trades.
- Service territory.
- Minimum or preferred project characteristics.
- Notification preferences.
- Consent and communication settings.

Customer dashboard

- Newly matched opportunities.
- Sort by relevance, freshness, estimated value, and distance.
- Filter by trade, jurisdiction, permit type, date, value, and confidence.
- Opportunity details.
- Match explanation.
- Source link and source timestamp.
- Save, dismiss, contact, and add note actions.
- Feedback control such as relevant or not relevant.

Notifications

- Daily email digest by default.
- Optional immediate email.
- Optional SMS for high-priority opportunities.
- Rate limits and quiet hours.
- Delivery and failure tracking.
- Duplicate-alert prevention.

Internal operations

- Source registry.
- Import history.
- Failed-record inspection.
- Classification review queue.
- User feedback review.
- Manual permit correction.
- Source freshness dashboard.
- Alert delivery dashboard.

7. Lead and opportunity definition

A permit record is not automatically a lead.

A customer opportunity exists only when:

1. A valid permit or construction activity record has been collected.

2. The record is sufficiently normalized.
3. The record matches an active customer's territory and trade criteria.
4. The system can explain the match.
5. The record is not excluded, stale, duplicated, or already suppressed.
6. Its confidence exceeds the publishing threshold or it has been manually approved.

8. Opportunity score

The first scoring system should be deterministic and explainable.

Example dimensions:

- Trade relevance: 0–30.
- Geographic fit: 0–20.
- Freshness: 0–15.
- Project value signal: 0–15.
- Customer filter fit: 0–10.
- Actionability and record completeness: 0–10.

Maximum score: 100.

Every score must retain a component breakdown. No opaque AI-generated score may directly control customer alerts during the MVP.

9. AI policy

AI may be used to:

- Interpret ambiguous permit descriptions.
- Suggest project categories.
- Suggest likely trade requirements.
- Summarize long descriptions.
- detect possible duplicate or related projects.
- Identify patterns for later analysis.

AI may not be the sole authority for:

- User permissions.
- Subscription access.
- Billing.
- Geographic inclusion.
- Notification consent.
- Record uniqueness.
- Regulatory decisions.
- Security decisions.

- Financial calculations.
- Destructive data operations.

Every AI classification must include:

- Model or provider identifier.
- Prompt or classifier version.
- Input reference.
- Proposed tags.
- Confidence.
- Evidence or explanation.
- Processing timestamp.
- Review status.

10. Confidence and escalation

Suggested classification policy:

- 0.90–1.00: Automatically publish when deterministic validations pass.
- 0.75–0.89: Publish only for noncritical descriptive tags or route through configured review rules.
- 0.50–0.74: Hold for human review.
- Below 0.50: Do not publish the proposed classification.

Thresholds are configurable business data and must not be hard-coded throughout the application.

Any security, identity, billing, legal compliance, or destructive-operation uncertainty must be escalated rather than inferred by AI.

11. Data source strategy

Every source integration must have a source profile containing:

- Jurisdiction.
- Source owner.
- Source URL or endpoint.
- Acquisition type.
- File or response format.
- Expected update schedule.
- Last successful acquisition.
- Parsing version.
- Known limitations.
- Terms or access review status.

- Failure escalation owner.
- Data fields typically available.
- Historical backfill capability.

Initial integrations should be intentionally narrow. A reliable single-jurisdiction pipeline is more valuable than several unstable scrapers.

12. Commercial model hypotheses

The initial commercial model should be tested rather than treated as finalized.

Potential packaging:

Pilot

- Restricted geography.
- Restricted trade set.
- Email alerts.
- Limited users.
- Direct founder support.

Professional

- More trades and filters.
- Faster alerts.
- SMS allowance.
- Saved opportunities.
- Reporting.
- Multiple users when implemented.

Market or enterprise

- Larger territory.
- Team routing.
- Exports and integrations.
- Custom sources.
- Service-level commitments.

Pricing must be validated against measurable customer outcomes such as hours saved, opportunities contacted, bids generated, and jobs won. Product development should not assume that record count alone supports pricing.

13. Defensible advantages

Potential defensibility comes from:

- Reliable Arizona source connectors.

- Historical normalized permit data.
- Fast detection and delivery.
- Trade-specific classification rules.
- Customer feedback data.
- Accurate geography and parcel resolution.
- Match-quality history.
- Local customer relationships.
- Operational knowledge of municipal source changes.

The dashboard interface alone is not a durable moat.

14. Success metrics

Data operations

- Source acquisition success rate.
- Time from source publication to ingestion.
- Parsing success rate.
- Duplicate rate.
- Address resolution rate.
- Percentage of records requiring review.
- Source freshness.

Intelligence quality

- Category precision.
- Trade-tag precision.
- Trade-tag recall.
- False-positive match rate.
- Customer-reported relevance.
- Score calibration.

Customer value

- Opportunities viewed.
- Opportunities saved.
- Opportunities contacted.
- Alert click-through rate.
- Time from alert to customer action.
- Customer-reported bids.
- Customer-reported jobs won.
- Weekly active customers.
- Trial-to-paid conversion.

- Retention and churn.

Notification health

- Delivery success.
- Duplicate notifications.
- Unsubscribe rate.
- SMS complaint rate.
- Alerts per user.
- Alerts ignored.

15. MVP exit criteria

The MVP should not expand to additional Arizona jurisdictions until the pilot demonstrates:

- Reliable recurring ingestion.
- Acceptable classification quality.
- Explainable matching.
- Low duplicate-alert rates.
- Evidence that pilot customers act on opportunities.
- Evidence that customers consider the information sufficiently timely.
- A repeatable process for repairing broken source integrations.
- A measurable willingness to continue paying or participating.

16. Explicit non-goals

The MVP will not:

- Automate permit applications.
- Guarantee that a permit becomes an available contract.
- Claim that a trade is definitely unassigned unless supported by the source.
- Generate or purchase personal contact information without an approved process.
- Contact property owners automatically.
- Publish low-confidence AI conclusions as facts.
- Use dozens of microservices.
- support every Arizona municipality.
- Implement every planned profile or analytics screen.
